

Digital 2-axis controller with integrated amplifier ED2

- optional for 4 proportional solenoids or 2 valves with the ± 10 V interface
- simple control via MPCS with the digital inputs and outputs
- integrated travel profiles generator (travel profile with acceleration, speed, deceleration and stop time)
- direct connection of analogue/digital measuring systems
- Fieldbus adaption possible (CAN/profibus DP)
- Parameters on card set with parameterising software PASO
- Multi-axis synchronous control by cross-linking

DESCRIPTION

Digital 2-axis controller in double Eurocard format (double-decker style). 2 plug connector terminal strips in accordance with DIN 41612, type F. Standard version with front plate with incorporated RS232 interface. The hardware can be expanded by means of plug-on modules. The software can be adapted to customer-specific requirements. The setting (parameterising and establishment of travel profiles) of the card is carried out in a user-friendly way with the parameterising software PASO.

FUNCTION

Digital 2-axis controller for the positioning of two axes. The setpoint position is predefined either externally (e.g., with a potentiometer) or internally by means of freely establishable travel profiles. As actual value transmitters, all standardized absolute and incremental measuring systems can be directly connected to the card. Numerous digital inputs and outputs enable the connection to a super-ordinate machine control system. Via the field-bus interface (CAN/profibus DP), the card can, e.g., communicate directly with, e.g., an MPCS. Furthermore the bus interface makes the interlinking of several 2-axis controller cards possible, so that up to 4 axis can be controlled synchronously.

APPLICATION

Typical applications for the digital 2-axis controller are control systems, where an accurately repeatable following of a travel profile is important or where a position has to be run up to and held several times. The travel profiles to be travelled can be established and stored by the user himself. As a result of its comprehensive equipment, the digital 2-axis controller can be flexibly and precisely adapted to any application.

BLOCK DIAGRAM

DESCRIPTION OF ED23X4D20-A (2-AXIS CONTROLLER)
Instruction

The axis controller ED2 is constructed as a double-layer Eurocard. All inputs and outputs have to be contacted to the connector. The version ED23 has a 9-pole plug for an RS 232 interface on the front plate, through which the configuration and the parameterization are carried out and through which also some diagnostic functions can be called up.

Function

The controller is designed as a digital 2-axis controller for the positioning of 1 axis or for the synchronised movement of 2 axis. The preset position can either be preset externally (e.g., by means of a potentiometer, only version ED231) or internally by means of freely adjustable travel profiles. As actual value transmitters all standardized absolute or incremental measuring systems can be directly connected to the controller. Several digital inputs and outputs enable the connection to a superordinate machine control system. Through the fieldbus interface (CAN/profibus DP), the controller can, e.g., directly communicate with an SMCS. The bus interface furthermore makes it possible to network several axis controllers.

- Manual operation
The control can be operate in the manual or automatic operation. In the manual operation, there are commands available for forward, backward, rapid speed, creep speed etc. With these commands it is possible to move the cylinders without a superordinate control
- Automatic operation
In the automatic operation, the cylinders will be moved either with the internally adjustable and selected travel profiles or with the externally given preset values (only version ED231).

The parameterization software (PASO) running under Windows provided together with the card makes it possible for the user to make various adjustments through the RS232 interface. The control characteristics can be adapted to the corresponding control system by means of various parameters. It is furthermore also possible to completely switch off the control system for test - and adjustment purposes.

Changed parameters are stored in a non-volatile memory, so that they are available once more after the controller has been switched on again.

Analogue inputs (only version ED231)

There are 4 differential inputs for preset or actual values available on the card. 2 are voltage signal inputs (voltage range $\pm 5\text{VDC}$ or $\pm 10\text{VDC}$), 2 are current signal inputs (current range $0/4 \dots 20\text{mA}$). The analogue signal is digitalized with 16-Bit.

Digital inputs

The digital inputs will be used for the control of the card. For example the travel profiles can be started, the connected cylinder can be moved manually etc. The digital inputs are „high-active“, opto-coupled and have to be connected to 24VDC for activation.

The following inputs are available:

- release control
- switch over between automatic/ manual operation
- choice between complete travel profile/sequence
- start/stop of a travel profile
- travel profile selection (4 inputs for 16 travel profiles, binary coded)
- choice between cylinder 1/cylinder 2 in the manual operation
- forward/backward in the manual operation
- rapid/creep speed in the manual operation
- search for reference for digital position measuring systems (encoder)
- single/synchronised movement in the manual operation
- limit switch positiv/limit switch negative
- reference switch

Inputs for the digital position measuring systems

The input/output interface provides the possibility of connecting different measuring systems to the axis controller.

- Absolute measuring systems
Temposonic systems with Synchron Seriell Interface (SSI)
- Relative measuring systems
Encoder systems with A+B track and a referenz-impuls track

Analogue outputs

The 4 solenoid outputs have a 1000Hz Pulse Width Modulated current output with superimposed dither. The polarity of the connected solenoids does not matter. The outputs are short-circuit-proof and can each be loaded with maximum 1.8 Amp. Additionally, the card has 2 analogue outputs. The analogue output 1, resp., 2 corresponds to the controller output value for the axis 1, resp., axis 2 and can be used to control a valve.

Digital outputs

The digital outputs serve for the remote signal for some conditions on a superordinate control. For example a control deviation or the position reached are noticed. The digital outputs are „high-active“, opto-coupled and have to be connected to 24VDC.

Travel profiles

The axis controller is in a position to save and to run through complete travel profiles, which have been preset by the user. A travel profile is a sequence of individual profiles (sequences). The travel command data of each sequence consist of:

- preset position (sequence target or endposition)
- speed (travelling preset speed value)
- acceleration (acceleration or deceleration, necessary for reaching travelling speed, starting from a given initial speed value)
- deceleration (deceleration or acceleration necessary for reaching the sequence end speed)
- stop time
- function "profile end reached" output

A travel profile as a minimum consists of one - and as a maximum of 100 sequences. As a maximum there are 16 travel profiles possible. A travel profile can be run through either completely or else step by step (sequence by sequence).

In the travel profile generator, the travel profiles can be adjusted and graphically displayed. This graphic display gives a good overview on the adjusted travel profiles.

Controller type

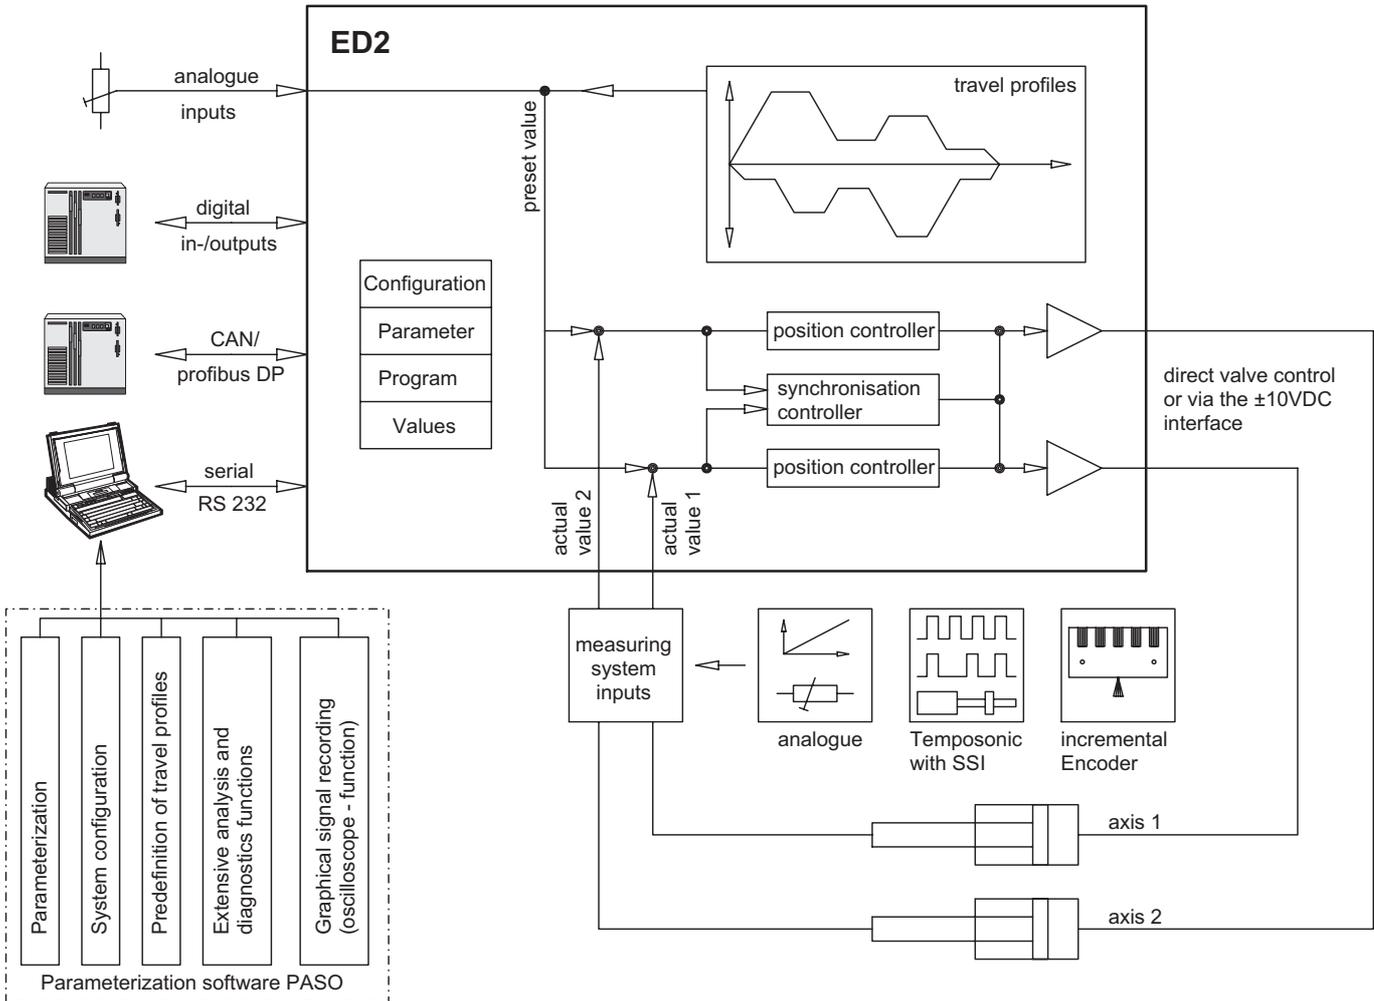

There are 2 controller types available:

- Position controller (1-axis application)
The function of the card is to control a position of one cylinder. The 2. cylinder is not active. The cylinder moves to the preset position and this position will be controlled. The control characteristic can be adjusted to the respective control system by means of various parameters.
- Synchronised movement (2-axis application)
The function of the card is to control a position of two cylinder. Both cylinders are active. The cylinders move synchronised to the preset position and this position will be controlled. The control characteristic can be adjusted to the respective control system by means of various parameters.

Signal recording

All relevant data (preset value, actual value, difference value etc.) of the connected card are read-in and displayed graphically (cathode-ray oscillograph function). It is possible to trigger to a desired signal. Also the sample time can be adjusted.
